Lab 10 - Functions that Modify Linked Lists

Objective

To develop some functions that operate on linked lists.

Attendance/Demo

To receive credit for this lab, you must demonstrate your work. **Also, you must submit your lab work to cuLearn by the end of the lab period.** (Instructions are provided in the *Wrap Up* section at the end of this handout.)

When you have finished all the exercises, call a TA, who will review the code you wrote. For those who don't finish early, a TA will ask you to demonstrate whatever code you've completed, starting about 30 minutes before the end of the lab period. **Any unfinished exercises should be treated as "homework"; complete these on your own time, before Lab 11.**

General Requirements

For this lab, you'll need your `linked_list` project from last week's lab. You should be able to download the zip file you submitted to cuLearn, but remember to extract the project from the compressed folder (don't try to edit and build a project that's stored in a compressed folder).

You have been provided with one file:

- `main_Lab10.c` contains a simple *test harness* that exercises the functions that you'll define in `singly_linked_list.c` during this week's lab. Unlike the test harnesses provided in previous labs, this one does not use the sput framework. The test code doesn't compare the actual and expected results of each test and keep track of the number of tests that pass and fail. Instead, the expected and actual results are displayed on the console, and you have to review this output to determine if the functions are correct.

The exercises in this lab are more challenging than the ones from Lab 9; however, all of the concepts you need to know have been discussed at length in the lectures. Before you attempt this lab, review the lecture materials on linked lists, and review the code you wrote for Lab 9.

Finish each exercise (i.e., write the function and verify that it passes all of its tests) before you move on to the next one. Don't leave testing until after you've written all your functions.

None of the functions you write should perform console input; i.e., contain `scanf` statements. Unless otherwise specified, none of your functions should produce console output; i.e., contain `printf` statements.

Instructions

1. Launch Pelles C and open the `linked_list` project you worked on during Lab 9. (If you don't have this project, follow the instructions in Lab 9 to create it.)
2. You don't need the test harness from Lab 9, so exclude `main.c` from the project. To do this, go to the Pelles C project window (the window that lists all the files in the `linked_list` project). In the list of source files, right-click on `main.c`, then select **Exclude** from the pop-up menu. A red circle with a slash will appear beside `main.c`, indicating that this file will not be compiled and linked in when the project is built.
3. You'll need the test harness for this week's lab, so download file `main_Lab10.c` from cuLearn. Move this file into your `linked_list` folder.
4. You must add `main_Lab10.c` to your project. From the menu bar, select **Project > Add files to project...** In the dialogue box, select `main_Lab10.c`, then click **Open**. An icon labelled `main_Lab10.c` will appear in the Pelles C project window.
5. Open `singly_linked_list.h` in the editor and add the following function prototypes at the end of the file:

```
IntNode *insert(IntNode *head, int index, int x);  
  
IntNode *delete(IntNode *head, int index);  
  
IntNode *delete_target(IntNode *head, int target, _Bool *removed);
```

6. Open `singly_linked_list.c` in the editor and add these function definitions at the end of the file:

```
IntNode *insert(IntNode *head, int index, int x)  
{  
    return intnode_construct(0, NULL);  
}  
  
IntNode *delete(IntNode *head, int index)  
{  
    return intnode_construct(0, NULL);  
}  
  
IntNode *delete_target(IntNode *head, int target,  
                        _Bool *removed)  
{  
    return intnode_construct(0, NULL);  
}
```

7. Build the project. It should build without any compilation or linking errors.

8. Execute the project. Read the console output carefully: look at the output printed in the console window and, for each test case, compare the expected and actual results. The test harness reveals that the three functions you just added to `singly_linked_list.c` do not produce correct results, which is what we'd expect, because these functions are incomplete. Read the `main` function, and determine what the tests do.

Exercise 1 (Difficulty Level: Moderate)

In `singly_linked_list.c`, finish the implementation of the `insert` function, which is passed a pointer to the first node in a linked list, a (non-negative) integer index, and an integer `x`. This function will insert a new node containing `x` at the specified index (position). The function prototype is:

```
IntNode *insert(IntNode *head, int index, int x);
```

Parameter `head` points to the first node in the linked list, or is `NULL` if the linked list is empty. The function **does not** terminate the program (via `assert`) if the linked list is empty.

This function uses the numbering convention that the first node is at index 0, the second node is at index 1, and so on. Parameter `index` must be in the range `0..length` (where *length* is the number of nodes in the linked list). If `index` is invalid, the function should terminate via `assert`.

Note that this function does not replace the contents of the node (if any) that is currently at position `index`. Instead, that node will be at position `index + 1` after the new node is inserted ahead of it.

The function returns a pointer to the first node in the modified linked list.

There are several cases you should consider when designing this function.:

- The linked list is empty. There are two subcases:
 - `index` is 0. The function will return a pointer to a list containing one node.
 - `index` is invalid.
- The function is passed a pointer to a linked list containing one or more nodes. There are four subcases:
 - `index` is 0. The function will insert the node at the front of the linked list.
 - `index` is greater than 0 and less than the number of nodes in the linked list. The function will insert a new node at the specified position.
 - `index` equals the number of nodes in the linked list. The function will append a new node after the last node.

- `index` is invalid.

Hint: you should be able to reuse parts of the algorithms from the `fetch` function you developed in Lab 9 and the `insert_front` and `append_rear` functions that were provided in `singly_linked_list.c`.

Build the project, correcting any compilation errors, then execute the project. The test harness will run. Inspect the console output, and verify that your `insert` function passes all the tests before you start Exercise 2.

Exercise 2 (Difficulty Level: Challenging)

In `singly_linked_list.c`, finish the implementation of the `delete` function, which is passed a pointer to the first node in a linked list and a (non-negative) integer index. This function will remove the node at the specified index (position) from the linked list, and deallocate the node via `free`. The function prototype is:

```
IntNode *delete(IntNode *head, int index);
```

Parameter `head` points to the first node in the linked list, or is `NULL` if the linked list is empty. The function should terminate (via `assert`) if the linked list is empty.

This function uses the numbering convention that the first node is at index 0, the second node is at index 1, and so on. Parameter `index` must be in the range $0..length-1$ (where *length* is the number of nodes in the linked list). If `index` is invalid, the function should terminate via `assert`.

The function returns a pointer to the first node in the modified linked list (this pointer will be `NULL` if the function deletes the only node in a linked list containing one node, resulting in an empty linked list).

There are several cases you should consider when designing this function.:

- The linked list is empty. The function will terminate via `assert`.
- The function is passed a pointer to a linked list containing exactly one node. There are two subcases:
 - `index` is 0 (the index of the first (and only) node). After the node is freed, the function will return `NULL`, indicating that the linked list is now empty.
 - `index` is invalid.
- The function is passed a pointer to a linked list containing two or more nodes. There are four subcases:
 - `index` is 0.

- `index` is greater than 0 and less than the index of the last node in the linked list.
- `index` is the index of the last node.
- `index` is invalid.

Hint: you should be able to reuse parts of the algorithms from the `fetch` function you developed in Lab 9 and the `remove_first` and `remove_last` functions that were provided in `singly_linked_list.c`.

Build the project, correcting any compilation errors, then execute the project. The test harness will run. Inspect the console output, and verify that your `delete` function passes all the tests before you start Exercise 3.

Exercise 3 (Difficulty Level: Challenging)

In `singly_linked_list.c`, finish the implementation of the `delete_target` function, which is passed a pointer to the first node in a linked list. The function removes the first node in a singly-linked list that contains an integer equal to the specified `target` value, and deallocates the node via `free`. The function prototype is:

```
IntNode *delete_target(IntNode *head, int target,
                      _Bool *removed);
```

Parameter `head` points to the first node in the linked list, or is `NULL` if the linked list is empty. The function **does not** terminate the program (via `assert`) if the linked list is empty.

If `target` is found, the variable pointed to by parameter `removed` should be set to `true`; otherwise it should be set to `false`.

The function returns a pointer to the first node in the list (this pointer will be `NULL` if the function deletes the only node in a linked list containing one node, resulting in an empty linked list).

There are several cases you should consider when designing this function.:

- The linked list is empty. For this case the function will return `NULL` (the target value cannot be in an empty linked list).
- The function is passed a pointer to a linked list containing exactly one node. There are two subcases:
 - `target` is in the first (and only) node. After the node is freed, the function will return `NULL`, indicating that the linked list is now empty.
 - `target` is not in the first (and only) node.
- The function is passed a pointer to a linked list containing two or more nodes. There are four subcases:

- **target** is in the first node.
- **target** is only in the last node.
- **target** is in the linked list, in any node other than the first or last nodes.
- **target** is not in the linked list.

Build the project, correcting any compilation errors, then execute the project. The test harness will run. Inspect the console output, and verify that your function passes all the tests.

Wrap-up

1. Remember to have a TA review and grade your solutions to the exercises, assign a grade (Satisfactory, Marginal or Unsatisfactory) and have you initial the demo/sign-out sheet.
2. The next thing you'll do is package the project in a ZIP file (compressed folder) named `linked_list.zip`. To do this:
 - 2.1. From the menu bar, select **Project > ZIP Files...** A **Save As** dialog box will appear. If you named your Pelles C project `linked_list`, the zip file will have this name by default; otherwise, you'll have to edit the **File name:** field and rename the file to `linked_list` before you save it. **Do not use any other name for your zip file** (e.g., `lab10.zip`, `my_project.zip`, etc.).
 - 2.2. Click **Save**. Pelles C will create a compressed (zipped) folder, which will contain copies of the the source code and several other files associated with the project. (The original files will not be removed). The compressed folder will be stored in your project folder (i.e., folder `linked_list`).
3. Before you leave the lab, log in to cuLearn and submit `linked_list.zip`. To do this:
 - 3.1. Click the **Submit Lab 10** link. A page containing instructions and your submission status will be displayed. After you've read the instructions, click the **Add submission** button. A page containing a **File submissions** box will appear. Drag `linked_list.zip` to the **File submissions** box. **Do not submit another type of file (e.g., a Pelles C .ppj file, a RAR file, a .txt file, etc.)**
 - 3.2. After the icon for the file appears in the box, click the **Save changes** button. At this point, the submission status of your file is "**Draft (not submitted)**". If you're ready to finish submitting the file, jump to Step 3.4. If you instead want to replace or delete your "draft" file submission, follow the instructions in Step 3.3.
 - 3.3. You can replace or delete the file by clicking the **Edit my submission** button. The page containing the **File submissions** box will appear.
 - 3.3.1. To overwrite a file you previously submitted with a file having the same name, drag another copy of the file to the **File submissions** box, then click the **Overwrite** button when you are told the file exists ("**There is already a file called...**"). After the icon for the file reappears in the box, click the **Save changes** button.

- 3.3.2. To delete a file you previously submitted, click its icon. A dialogue box will appear. Click the **Delete** button., then click the OK button when you are asked, "**Are you sure you want to delete this file?**" After the icon for the file disappears, click the **Save changes** button.
- 3.4. Once you're sure that you don't want to make any changes, click the **Submit assignment** button. A **Submit assignment** page will be displayed containing the message, "**Are you sure you want to submit your work for grading? You will not be able to make any more changes.**" Click the **Continue** button to confirm that you are ready to submit your lab work. This will change the submission status to "**Submitted for grading**".
